days. The three severely thrombocytopenic neonates did not manifest a hemorrhagic syndrome and spontaneously recovered a normal platelet count within 2 weeks. Occasional fetal morbidity or mortality from hemorrhagic complications of ITP during pregnancy encourage some authors to favor the use of PUBS. Other authors argue that the risks associated with PUBS are greater and recommend determining the route of delivery by maternal obstetric indications.

Our encouraging experience provides further evidence that in skilled hands PUBS may be useful in the management of pregnant women with ITP, providing a safe way to guide the mode, site and time of delivery.

Adenovirus infections are a frequent cause of severe complications in the post allogeneic bone marrow transplantation period, and to date, no established form of treatment exists. We report the case of an autologous bone marrow transplant recipient who developed adenovirus pneumonitis which was successfully treated with intravenous ribavirin.

Since conditioning regimens largely ablate virus specific immunity, there may be a reactivation of latent viruses such as adenovirus. The incidence of adenovirus infection in BMT recipients, according to the largest published review was 5% although it may be as high as 18% in the pediatric population, in second place after herpes simplex. When disseminated adenovirus infection occurs, it mainly affects the urinary tract, liver, gut and lungs, and can prove fatal in half the cases.

Adenovirus is more common after an allogeneic transplant, and a significant relationship between post-transplant adenovirus infection and the occurrence of acute graft-versus-host disease has been described. We present the case of a patient who developed adenovirus pneumonitis after undergoing an autologous BMT, and who was successfully treated with intravenous ribavirin.

A 43-year-old man with acute myeloid leukemia in first remission underwent autologous BMT using TBI (13.2 Gy) and CY 60 mg/kg two day conditioning. On day 0, 300 cc of autologous bone marrow was infused with CMN 2.17×10^6/kg and CFU-GM 4.34×10^6/kg. On day +20, after persistent fever without an identifiable focus treated with imipenem-teicoplanine-amptherocerin B, he developed a persistent non-productive cough, dyspnea, hypoxemia, a

worsening in his general condition, as well as painful hepatomegaly. Analysis showed bilirubin 3.7 mg/dL (normal values up to 1) LDH 638 U/L (normal values up to 460); chest X-ray revealed diffuse alveolar-interstitial infiltrates. The BAL performed ruled out *Pneumocystis carinii*, HSV, RSV, CMV, Legionella, BARR or fungal infection. The echocardiogram showed no abnormalities. Saline restriction measures were taken and diuresis was stimulated but the patient’s condition did not improve.

On day +28 he was transferred to the intensive care unit. One day later, adenovirus was isolated in BAL, so i.v ribavirin was administered along with assisted ventilation; 48 hours later the fever disappeared and a marked improvement was observed in breathing and liver function. Total resolution occurred on day +37. The ribavirin dosage administered was 15 mg/kg every 6 hours for 8 days. A further BAL was carried out on day +46 which was negative for adenovirus. The leukocytic graft reached 1,000 leukocytes with 500 granulocytes on day +29, fell to 200 on day +36 which required G-CSF and remained at < 500 granulocytes up to day +48.

Although adenovirus may remain present in tonsillar and other lymphoid tissue for prolonged periods, if isolated from a BAL done under optimal conditions in which no other pathogens can be found, this can be considered diagnostic of acute adenovirus. To date, the efficacy of intravenous ribavirin has been demonstrated in adenovirus infections such as cystitis, nephritis, gastroenteritis, pneumonia, and disseminated adenovirus infection. The dosage employed by most authors varied between 15 and 30 mg/kg/d divided in three doses. In our case, following Wulffraat et al., we administered a dosage of 15 mg/kg/6 h (a total dosage of 60 mg/kg/d), which led to rapid clinical improvement and clearance of adenovirus infection. This did, however, have a negative effect on the leukocytic graft which, fortunately, was reversible. The hematologic effects of ribavirin have been investigated in Rhesus monkeys. Mild normocytic anemia or severe anemia occurred when ribavirin was administered at dosages of up to 30 or 50 mg/kg/day, respectively; however, no significant effects were observed on white blood cells. Like other authors, we consider that intravenous ribavirin is an effective treatment for adenovirus infection, but believe it is necessary to determine the exact dosage at which toxic effects are avoided but efficacy is maintained.

We give the first description of portal and mesenteric venous thrombosis associated with the 20210 A allele of the prothrombin gene in a 48-year-old woman after splenectomy.

Recently, the 20210 A mutation of the prothrombin gene has been described in patients who have had venous thromboses in unusual sites, such as the superior sagittal sinus and in the Budd-Chiari syndrome. Mesenteric thrombosis in patients with idiopathic thrombocytopenic purpura (ITP) undergoing splenectomy is uncommon. The usually transient post-splenectomy thrombocytosis has a not well defined effect on the development of thromboembolism.
